GENERAL FEATURES

"V230" valves are the essential elements in building the following systems:

- a) simplex, duplex or multi-tank softening (decalcification) systems for domestic, laboratory and industrial use;
- b) simplex or duplex demineralisation and dealkalisation systems for laboratory and industrial use and all other uses requiring water with characteristics of guaranteed quality;
- c) simplex or duplex filtering systems for all of the previous applications.

The valves are made with materials that guarantee utmost resistance and quality. They are available with a vast range of controllers for every operation phase of service and regeneration, starting from the simplest electronic basic controller with weekly clock to the sophisticated electronic controllers in various models which enable volume, volume-time control and salinity control in MicroSiemens/cm, etc.

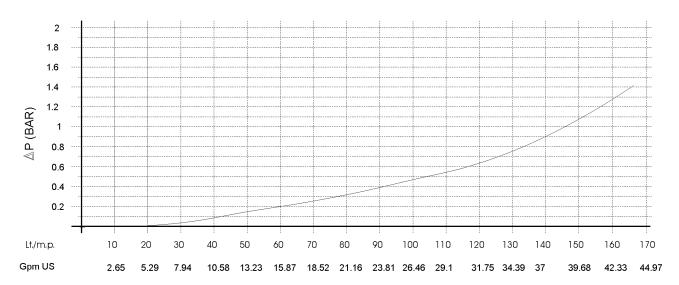

In the electronic systems, all the intervention times of operation phases can be programmed in relation to system type and dimension.

For specific controller features, see the relative manual.

TECHNICAL SPECIFICATIONS

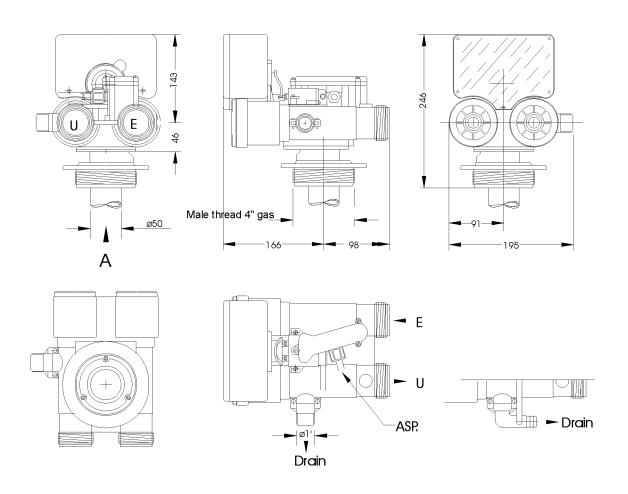

Operating pressure	From 1.5 to 6 bar
Maximum water flow with load loss of 1bar	44.09 US gpm. 25.7 UK gpm
See Table 1 for value variables	-
Backwash water flow	max. 17.64 US gpm 11
Slow rinse water flow	0.44 to 2.65 US gpm 0.16
Fast rinse water flow (down-flow)	max. 24.25 US gpm
Static resistance to pressure	22 bar
Maximum quantity of regenerative resin	200 l.
Operating temperature	From 5 to 40 ℃
Materials of main components	ABS+FV
Tank connection	Ø 4"
Input output attachments	2" gas male

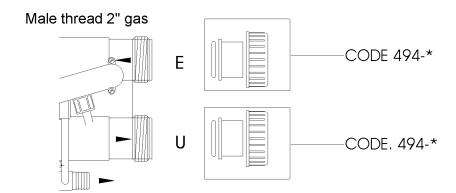

PRESSURE DROP

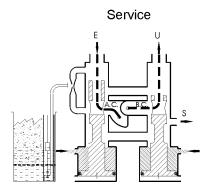

For cod. 494-* see page 24

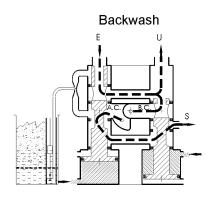

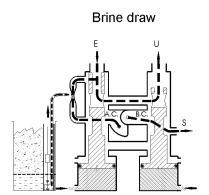

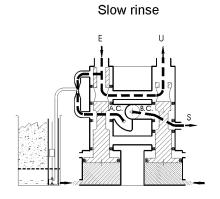

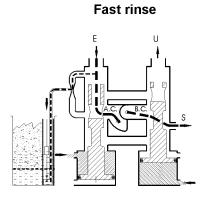

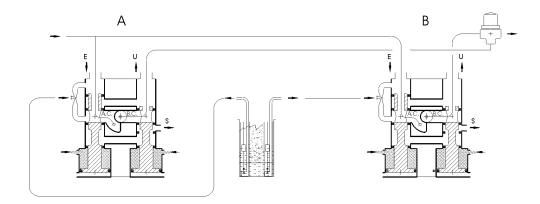

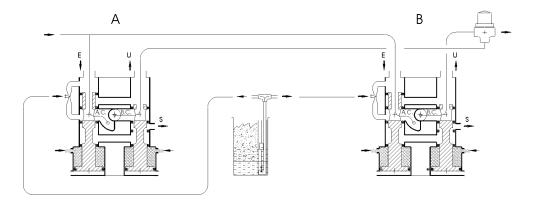

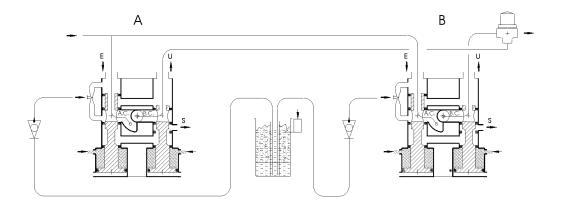

A) Duplex softening scheme with two brine measure valves, slow rinse,3V output valve. 5 pilot valve controller.

B) Duplex softening scheme with brine measure valve, slow rinse and automatic/dynamic device to determine brine-draw line. 5 pilot valve controller. 3V valve.

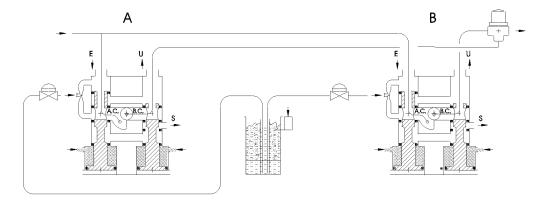

C) Duplex softening scheme without slow rinse, (salt-brine container fed separately), without brine-measure valve. 5 pilot valve controller. 3V valve.

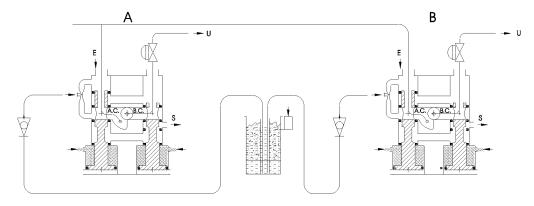

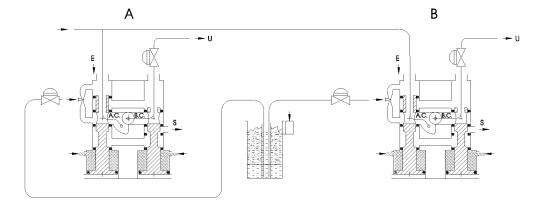

E) Duplex softening scheme with slow rinse (Salt/brine container fed separately) without brine-measure valve. 7 pilot valve controller. 3V valve.

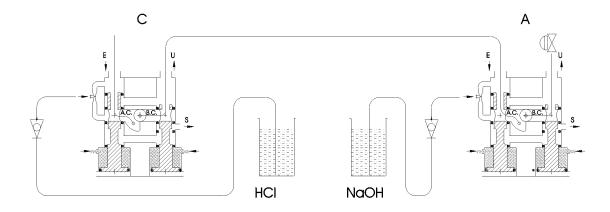

F) Duplex softening scheme without slow rinse (Salt/brine container fed separately) Two output valves "A" and "B". 5 pilot valve controller. Without brine measure valve.

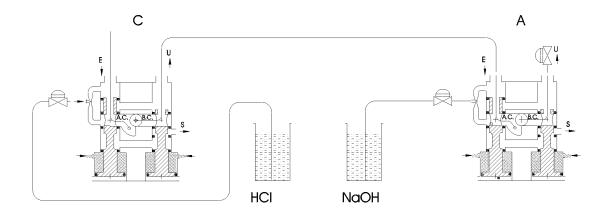

G) Duplex softening scheme with slow rinse (Salt/brine container fed separately) Two output valves "A" and "B". 7 pilot valve controller. Without brine measure valve.

H) Demineralisation scheme without valves for slow rinse, 5 pilot valve controller. Attention! Dissuaded application

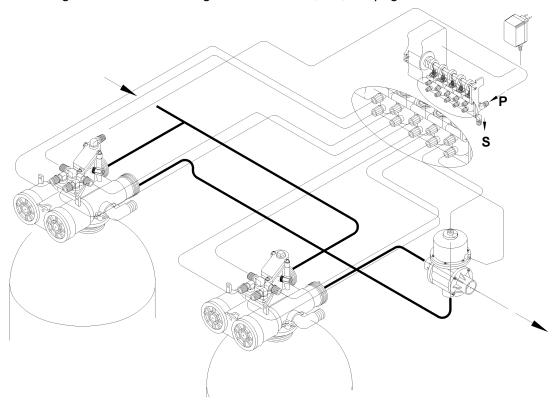

I) Demineralisation scheme with valves for slow rinse, 7 pilot valve controller. Attention! Application Recommended

AUTOMATIC BY-PASS FOR DECALCIFIERS

Service with Elevated pressure drop After the Tank Valve

BY-PASS FOR FILTERS

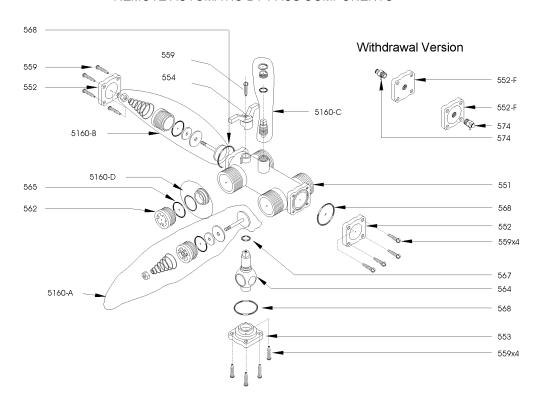

Remote By-pass for Filter

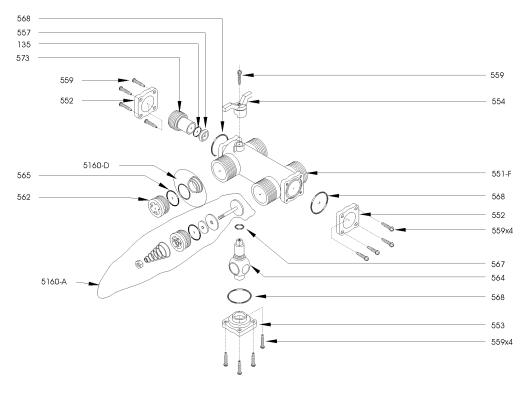

Code BV-FR

REMOTE AUTOMATIC BY-PASS COMPONENTS

REMOTE BY-PASS COMPONENTS FOR FILTRATION

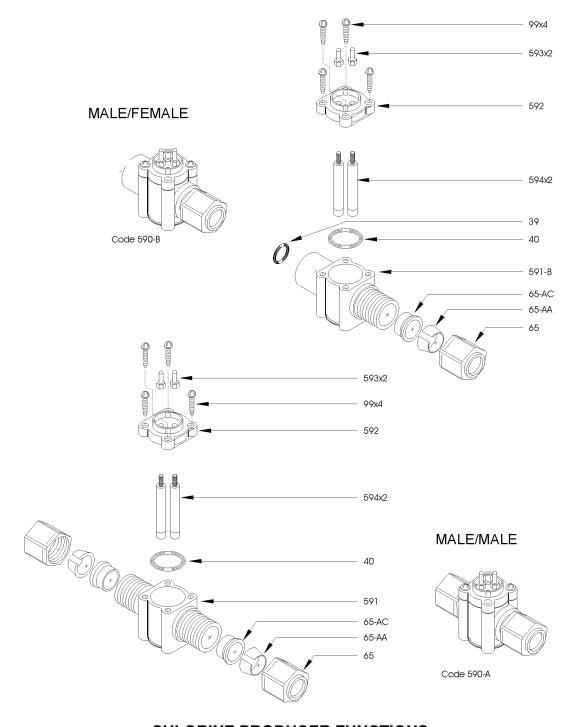

AUTOMATIC BY-PASS FUNCTIONS

Proportional automatic by-pass functions consist in performances that facilitate system service with the following functions:

- a) delivery of untreated water during regeneration phases;
- b) partial delivery of water under use and service when withdrawals momentarily are higher than normal; Example: a momentary increase in water consumption creates a drop in pressure after the softening tank. The drop in water pressure as it comes out of the softener causes the automatic by-pass valve to open partially, making up for the increased demand.
- c) the by-pass has a mixer which, regulated to system functioning, obtains a residual hardness value in treated water in conformity with norms.
- d) in the event the system is equipped with a chlorine producer, it is advised to use a BVRPOD by-pass with incoming and outgoing withdrawal, so as to perform the checks set out in DPR 443.
- e) the by-pass makes it possible to exclude the valve or the entire system without interrupting water delivery.

CHLORINE PRODUCER COMPONENTS

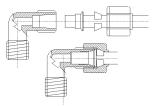

CHLORINE PRODUCER FUNCTIONS

The chlorine producer is characterised by the possibility to automatically sterilise resin with each regeneration. For this function, of course, the valve must be equipped with the appropriate "cloro" electronic timer. This controller feeds electrically, during the phase of regeneration 2C, the cell electrolytic, producing so for the duration of the phase chlorine or is mixtures. The duration of the phase 2C rule so the quantity of chlorine that is necessary for the sterilisation of the resins.

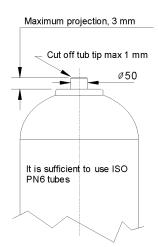

TIPS AND SUGGESTIONS

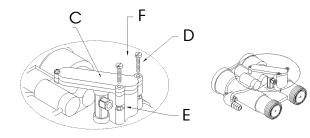

In connecting tubes and joints, using 1/8" ø 9.7 mm rigid or flexible tubes, respect tube size. Tubes of smaller dimensions can not guarantee retaining quality to pressure or pressure loss. Tubes of larger dimensions can force the housing and compromise the mounting of blocking rings and retaining quality as well.

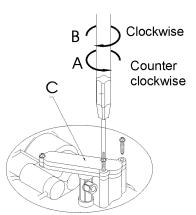

In performing interventions on existing connections, always use new retaining rings, cod. 65-AC 65-AA. In assembling, take care that the tube end fully enters the housing to guarantee the best grip.

In the case of flexible tubes, screw on the nut tightly using only one's hands and then, if necessary, a wrench. In using rigid tubes, use a wrench.

Disassembly and reassembly of selfthreading screws

PRECAUTIONS IN DISASSEMBLING "C" COLLECTOR

In disassembling the "C" collector, unscrew the screws slowly to avoid gripping between materials and screws.

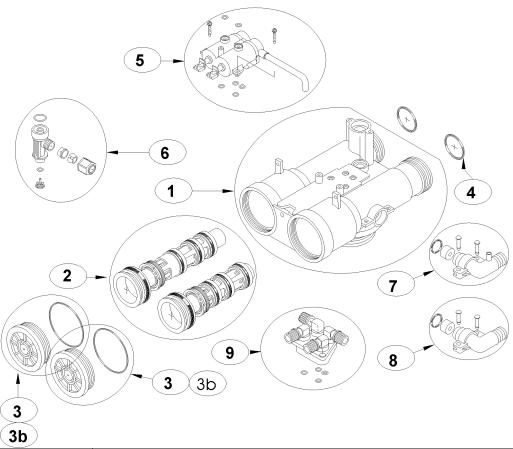

Before remounting, carefully clean the hole and screws. Insert the screw in the hole and by hand, slowly turn it in direction "A" until reaching the beginning of the thread, then turn the screw in direction "B," still by hand, without forcing it.

Using a screwdriver, slowly screw in direction "B" until tight; do not force. Always perform these operations using normal screwdrivers; do not use automatic screwdrivers.

MODIFICATION TO PERFORM IN CASE OF DAMAGE TO THREADED HOUSING OF "F" SELF-THREADING SCREWS

If during disassembly and reassembly of the "C" collector, the threads of the "F" screw housing, make a hole as indicated in "E," using a flat or squared large-grain file, 3 or 4 mm thick. Insert a 3M nut in this hole and replace the "F" screws with M3 "D" screws of the proper length (minimum 15 mm).

INTERVENTIONS OF ORDINARY MAINTENANCE

drawback	cause	corrective action
leakage from drain during the service	leakage from the pilot	1) - to close water in entrance 2) - to close water in exit. 3) - to detach the tube of connection between the pilot and the drain collector. 4) - to remove the three screws that keep down the collector code 022 page. 9. To remove the two O-R 058 page. 9 and to replace them with two diskettes in soft rubber, thickness around 2mm. Or closing the passage with a thin sheet of plastic. 5) - to reassemble the collector 022, tightening the three screws taking care not to force. 6) - to reopen the inlet and the outlet of the water. Completed the procedure, if the leakage to drain has disappeared, the drawback is due to the pilot. In this case it's necessary a substitution. If the leakage persists, the cause could be owed to a leakage of the chambers of the main cylinders. To identify the defective chamber, to proceed as to the 4 point, to close only one of the two O-R 058 beginning from the left one. the same operation will be effected, eventually, also for the right chamber.
		The indication of what chamber is defective is the disappearance of the leakage, in relationship to the closed side of the pilot. To eliminate the defect, it is necessary to take a part the defective chamber, proceeding as below: a) to -close water inlet and outlet b) to -unscrew the cap of the defective chamber using the special tool or seeger pliers. The maintenance kit contains the right tools for the interventions of maintenance. c) - to remove the stem of the pilot of the side related to the chamber. d) - to extract the piston with a pliers, take out the inside pivot. e) -to -verify that there are not scratches or other damages on the stem of the piston. f) -if evident defects are not found on the piston, to unscrew the blockage ferrule of the spacer package, and to verify the state of the O-R 043-044-048 pag.9. If there isn't damage, it's advisable to replace all the gaskets O-R, verifying carefully the state of all. In the case to proceed is necessary to the complete removal of the spacer package, take care at the moment of the reassembly, to check the exact position page. 9.
	Leakage from external command pilot	Also this may be detected through a simple test: Disconnect, in service position, pressure connectors 2 and 4 alternatively. In case some water should leak from one of the pressure connectors from the pilot body, it means that the related pilot has some leaks and must be replaced. If the leakage is not due to the pilots, its cause has to be ascribed to a possible leakage of valve piston.
	leakage of her valve through the system of the pistons	In the case the leakage is found to originate only from the collector of draining, it is possible to determine easily in what chamber / piston there is the leakage. 7) -if the water of leakage to drain is hard water, it is due probably to the O-R of the ferrule 012 (043-044-048), inlet side, page. 9. Phase service pag.7. 8) - if the water of leakage to drain it results soft water, to replace the third O-R after the ferrule, page. 7 phase service. To effect this intervention, to proceed as suitable to the point 6 paragraphs "a,b,c,d,e,f."
Hardness' escape To the exit	probable leakage between entrance and exit O-R on the kept ac/bc	9) -to extract the piston of the entrance, to check that there are not damages evident on the surface. if the piston results damaged, to replace it. Otherwise I would replace the first O-R departing from the end of the stem piston (entered). Page. 7 and 9. to effect this intervention, to proceed as suitable to the point 6°, paragraphs "a,b,c,d,e,f." 10) - to remove the valve from the cylinder, to replace the O-R 046 that it operates the estate between the top column and the pipe of the down column.
It doesn't inhale brine	lack of pressure	11) -to close the entrance to the valve, verifier that the manometer points at one non inferior pressure to 2 bar, if it results inferior, the pressure is insufficient. 12) - if to the point 11 the pressure is superior to 2 bar, to check the state of stoppage of the mechanical filter, installed to the entry of the plant. To get off it and to polish up. If after this operation the problem has not resolved, to proceed with the point 13.
	obstruction pre filter over pilot. obstruction perforate injector. problems to the brain tank	13) -to remove the collector 022 page. 9, to extract the filter 018 and to polish up it carefully, therefore to proceed to the point 14. 14) -to remove the injector 060 page. 9, to polish up the holes of the same carefully and to reassemble everything. 15) -if after this actions, the problem has not been eliminated, proceed to an accurate control of the complex connections and brine tank: g) -to check that there are not obstructions in the system of connection. h) -to check that the pole of the craft forced toward the lower part, disburses water. i) -to check that the salt of the container, is not become hard. j) -verify that the brine valve works in all regularly its components, doesn't have leakage on some terminal or link.
